

Biodiversity and Information

Jonathan Silvertown (keynote speaker)

Professor of Ecology, The Open University

Biodiversity is defined the richness of life at all levels of organization from genes through species to ecosystems. Ecologists often use the Shannon function to measure diversity at the level of population genetics and species diversity, explicitly measuring the information content at these levels. I will give a brief overview of the hierarchy of biological organization and then illustrate this with some of my own work in plant ecology and evolution.
